evolving devp2p

Felix Lange (Ethereum Foundation) Nov 2, 2017 *libp2p (aka DEVp2p) aims to provide a lightweight abstraction layer that provides these low-level algorithms, protocols and services in a transparent framework without predetermining the eventual transmission-use-cases of the protocols.* – DEVp2p Whitepaper Wiki Page

• We should probably delete this wiki page ;)

- Part of all known Ethereum implementations
- Very few protocol changes since 2014
- Elements
 - Node Discovery
 - Transport (RLPx)
 - Application Layer (devp2p)

v4: A lonely node

v4: Connecting to the DHT

v4: Finding other nodes

v4: Connecting via TCP

v4: Negotiating devp2p capabilities

v4: Exchanging eth information

- So many roundtrips!
- Upgrades need tight coordination
 - · Everything needs to be backwards-compatible
 - · Past upgrades tied to Ethereum mainnet hard forks
- Stuck with RLPx, secp256k1, keccak256

Node Discovery v5

- · Finding nodes more efficiently
- · Knowing more about those nodes before we connect

- Ethereum Node Record
- Replaces enode://...
- RLP [sig, seq, key, value, key, value, ...]
- At most 300 bytes
- Signed (sig), Ordered (seq)

- key, value arbitrary
- Node identity, transports encoded in key, value
- · RLPx remains common transport for now
- Sunset RLPx when there is a viable alternative
- We can try ipfs/libp2p transports

Similar to v4, but:

- ENR
- Remove dependency on absolute time
- Require endpoint proofs to reduce dead/spam nodes

- + v4 DHT: public key ightarrow address
- Topic index: topic \rightarrow nodes

- One DHT for everyone
- · Scale to arbitrary number of topic members
- · Should deal with spam

- · When advertising a topic, there is an artificial delay
- Combats many attacks, reduces misuse
- · Use topics for announcing big decisions

- Prototype (without ENR) used by geth --light
- EIPs forthcoming
 - ENR
 - Topic Ad Protocol
 - Discovery v5 Wire Protocol
- Nothing set in stone yet, come talk to us!

Thank You
